

twelve sheets over V in six version pairs $\{gX, gbX\}$; a lift of ℓ_s from the sheet gX ends on the sheet gsX

$$t^3 = b^2 = E, \quad btb = t^{-1}, \quad bt = t^2b \neq tb$$

continuation along ℓ_s multiplies the sheet label on the right

the six t, b -sheets as a graph:
 t then b reaches tbX , b then t reaches t^2bX ; the u -half is alike

two configurations over one point $[X]$:
 no rotation carries X to bX (best-fit residual 0.76 Å); the action is free near X_0 (nearest image 2.30 Å away)
