

$$\Psi(\sigma X) \sim \chi_{\text{stat}}(\sigma) \sigma \cdot \Psi(X), \quad \chi_{\text{stat}}(\sigma) = \prod_{\alpha} (\text{sgn } \sigma_{\alpha})^{2I_{\alpha}}: -1 \text{ for } ^1\text{H}, +1 \text{ for } ^2\text{H}, ^{16}\text{O} \text{ not permuted}$$

$\Psi(E^* X) \sim \pm \Psi(X)$ on $\mathcal{H}^{\pm}$: parity is a separate character, $\chi_{\pm}(\sigma^*) = \pm 1$, and χ_{stat} ignores the star

equalities hold almost everywhere on $\mathcal{C}$; the physical space $\mathcal{H} \subseteq \mathcal{H}_{\text{ambient}}$ is cut out by these two conditions
