

methylamine: one fragment, or two; a boundary is drawn on the configuration, the positions do not move

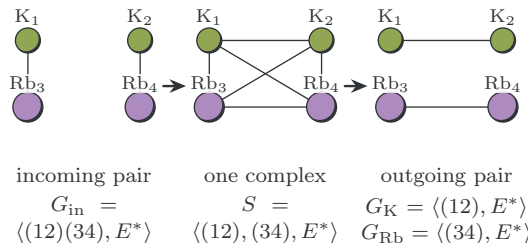

relative position and orientation of the fragments remain coordinates in $\mathcal{C}$; rigid fragments are a modelling approximation

the 16 subgroups of $S \cong C_2^3$, by order; the three channel groups, their common core $\langle E^* \rangle$ and S in black; any two channel groups generate S ; this is inclusion, neither accessibility nor yield

order 1

KRb + KRb: three groupings of the same four nuclei, potassium 1, 2 and rubidium 3, 4; a line joins grouped nuclei (positions schematic)

each channel group has order 4; grouping is not bond formation
